## To Help Jaguars Survive, Ease Their Commute

Steve Winter/Panthera

A jaguar in the Pantanal, Brazil, the world's largest wetland.

The New York Times Steve Winter/Panthera  
A representative of Panthera teaches schoolchildren in Bajo del Tigre, Costa Rica, about conservation efforts for jaguars.

"I understand cats do this because they need to survive," said Mr. Porrás-Valverde, 41, a burly dairy farmer.

A few years ago, he acknowledged, his first reaction might have been to reach for a gun. But his farm now sits in the middle of land that Costa Rica has designated a "jaguar corridor" — a protected pathway that allows the stealthy, nocturnal animals to safely traverse areas of human civilization.

In the past few years, such [corridors](#) have been created in Africa, Asia and the Americas to help animals cope with 21st-century threats,

from encroaching highways and malls to [climate change](#).

These pathways represent an important shift in conservation strategy. Like many other nations, Costa Rica has traditionally tried to protect large mammal species like jaguars by

## [The Path of the Jaguar](#)

A New Paradigm in Big Cat Conservation

“It was kind of an epiphany,” said Alan Rabinowitz, a zoologist who is president of [Panthera](#), an organization that [studies](#) and promotes conservation of large cats. “We were giving them nice land to live on when what they were doing — and what they needed — was an underground railway.”

He said critical migration routes were especially vulnerable in rapidly developing countries, where new roads, shopping malls, dams, playgrounds and subdivisions could spring up overnight, blocking the animals’ passage. To correct this oversight, Costa Rica and other countries have begun identifying and protecting corridors for jaguars and other large mammals, like tigers, snow leopards and pandas.

Most of the corridors are not obviously demarcated pathways, but virtual trails, “protected” in the sense that builders and planners are not permitted to introduce obstacles to the animals’ movements through the area.

The idea is not to stop building entirely, but to adjust development so that animals can move through landscapes that humans also occupy. A tall fence surrounding a shopping mall may be forbidden, for example, or a two-lane road may have to be substituted for a proposed four-lane highway.

Local residents must also be persuaded not to shoot wild intruders or otherwise drive them away when they are in transit, a shift in thinking that is already taking root here.

“Of course jaguars sometimes have conflicts with communities, but now people have been educated to change their thinking — not to see them as so dangerous,” said Víctor Fallas Ramírez, an agronomist who grows ornamental plants here.

The threat of global warming has added to the urgency of creating corridors because animals will need to shift habitats as temperatures rise from climate change.

“This is an idea that people are finding very compelling, and especially compelling now because with changing climate, species will need the capacity to move,” said [Norman Christensen](#), a professor of ecology at [Duke University](#), whose team is working to define corridors in Central America, India and Africa.

While Dr. Christensen called Costa Rica “the poster child” for its efforts, he said corridors for large mammals were also being created in places like Uganda and China. The [World Bank](#) is financing corridor projects in [Brazil](#) and [Peru](#); more important, the bank’s transportation planners are working with conservationists to ensure that building highways and laying train tracks so humans can move freely does not destroy that

creating sanctuaries — buying up land and giving threatened animals a home where they can safely eat, fight and breed to eternity.

But in the past decade or so, scientists have realized that connecting corridors are needed because many species rely for survival on the migration of a few animals from one region to another, to intermix gene pools and to repopulate areas devastated by natural disasters or disease. Placing animals in isolated preserves, studies have found, decreases diversity and risks dulling down a species — like preventing New Yorkers and Californians from getting together to procreate.

movement for animals, Dr. Christensen said.

Part of the reason that conservationists had in the past focused exclusively on preserves was that there was a lack of good data on the travel and breeding patterns of large animals like jaguars; these big predators favor dense jungles and are nocturnal and extraordinarily shy.

So when new techniques allowed scientists to take a first look at the jaguar genome a decade ago, they were shocked to discover that jaguars from the northern reaches of Mexico had exactly the same genetic makeup as those from the southern tip of South America.
